

Plants Module — Data Consumers Mapping

Delwende Esther Wangre — Infineon / BIT Excellence Program — Plants Module

Prepared following JF feedback (24/07/2026): "list what are the important aspects of the Plants app and think which aspects are needed for which partner downstream in the supply chain."

Purpose

This document identifies which data produced by the Plants module is needed by which downstream module in the supply chain, and why. It answers the feedback received on 24/07/2026 from Hans and Abdo. It does not replace the generic API design already defined (resource-based endpoints, not consumer-specific ones) — it simply makes explicit, in a readable form, who the current known consumers are and what they need.

Data → Downstream Partner Mapping

Plants data / aspect	Format	Downstream module	Why it is needed
Harvest record (id_lot, quantite_kg, date_recolte, variete)	JSON (via API)	Product Transformation (Abdoul)	The harvest is the direct input to the transformation process; id_lot is the pivot for traceability.
Harvest by lot / bloc_parcelle (quantite_kg, id_lot, bloc_parcelle)	JSON (via API)	Crop Storage (Christelle)	Stock tracking needs to be linked to the originating lot and block for accurate inventory management.
Growth stage / phase, planting date, bloc_parcelle	JSON (via API)	Water Supply (Yienouyaba)	Irrigation needs vary by growth stage and by block; this data allows irrigation to be adjusted accordingly.
Disease detection result (health %, category, bloc/arbre)	JSON (via API)	Fencing & Security (Filomene) — incoming, not outgoing	Plants receives this data rather than producing it; listed here for completeness of the data flow.
Variety reference data (name, expected yield, spacing)	JSON (via API), Swagger-documented	Any future/unknown module	Exposed as a generic resource (GET /varietes) so any new module can self-serve without custom endpoints.

Design principle behind this mapping

The Plants API is not designed around these three modules specifically. Data is exposed through generic, resource-based endpoints (e.g. GET /recoltes, GET /varietes, GET /sante-arbres), documented automatically via Swagger, so that any future module can consume what it needs without a custom-built endpoint. The three consumers listed above are simply the ones already identified as probable users of this data at this stage of the project.

Source

Based on the API design already defined for the Plants module (generic resource exposure, JSON format, versioned API) and on the task/module list confirmed at kick-off.
